

Assignment Using R and Python

Name: Md. Nahid Hasan

ID: 12110005

Department of Statistics

Begum Rokeya University, Rangpur

1. Consider the lung cancer data and solve the following questions using Python.

Basic EDA Questions i) Summarize the distribution of Age. Is it normally distributed or skewed? ii) What proportion of individuals are smokers vs non-smokers? iii) Which income group has the highest frequency? iv) What percentage of individuals are exposed to high pollution? v) What is the overall prevalence of lung disease?

Association & Crosstab i) Is there an association between Smoking and Lung Disease? ii) Interpret using a contingency table. iii) Does Pollution level affect Lung Disease? iv) Compare lung disease prevalence across Income groups. v) Which factor appears to have the strongest relationship with lung disease?

Statistical Testing i) Perform a Chi-square test for: Smoking vs Lung Disease and Pollution vs Lung Disease. ii) When should you use Fisher's Exact Test instead of Chi-square? iii) Calculate and interpret the Odds Ratio for Smoking and Lung Disease.

Correlation & Interpretation i) Interpret the correlation between: Smoking and Lung Disease, Age and Lung Disease. ii) Why is correlation not sufficient for causal inference?

Logistic Regression i) Fit a logistic regression model: Lung Disease ~ Smoking + Age + Pollution + Income. ii) Which variables are statistically significant predictors? ii) Interpret the odds ratio of Smoking. iii) What happens to the effect of Smoking after adjusting for Pollution?

Advanced Modeling i) Add an interaction term (Smoking x Pollution). ii) Is the interaction significant? iii) Interpret the interaction: Does pollution amplify smoking risk?

Research question: using the lung disease dataset, perform exploratory data analysis and fit a logistic regression model to identify key determinants of lung disease. interpret your finds and discuss public health implications. now give solution using python

2. Suppose we want to determine if three different exercise programs impact weight loss differently. We recruit 90 people to participate in an experiment in which we randomly assign (using uniform distribution) 30 people to follow either program A, program B, or program C for one month. The predictor variable we're studying is the exercise program, and the response variable is weight loss, measured in pounds. Conduct a one-way ANOVA to determine if there is a statistically significant difference between the resulting weight loss from the three programs, check the model assumptions, and analyze treatment differences.

```
[11]: #Read Data
import numpy as np
import pandas as pd

np.random.seed(123)

# Generate uniform data
A = np.random.uniform(3, 7, 30)    # Program A
B = np.random.uniform(4, 8, 30)    # Program B
C = np.random.uniform(5, 9, 30)    # Program C

# Combine into DataFrame
data = pd.DataFrame({
    'weight_loss': np.concatenate([A, B, C]),
    'program': ['A']*30 + ['B']*30 + ['C']*30
})

print(data)
#Summary Data

data.groupby('program')['weight_loss'].describe()
#Normality Check
from scipy.stats import shapiro

for group in ['A', 'B', 'C']:
    stat, p = shapiro(data[data['program'] == group]['weight_loss'])
    print(f"Program {group}: p-value = {p:.4f}")

#Variance check
from scipy.stats import levene

stat, p = levene(A, B, C)
print("Levene p-value:", p)

#One way ANOVA
from scipy.stats import f_oneway

stat, p = f_oneway(A, B, C)
```

```

print("F-statistic:", stat)
print("p-value:", p)

#Visualization
import seaborn as sns
import matplotlib.pyplot as plt

sns.boxplot(x='program', y='weight_loss', data=data)
plt.title("Weight Loss by Program")
plt.show()

```

	weight_loss	program
0	5.785877	A
1	4.144557	A
2	3.907406	A
3	5.205259	A
4	5.877876	A
..	...	...
85	8.366680	C
86	6.429590	C
87	5.174366	C
88	6.219072	C
89	6.592743	C

```

[90 rows x 2 columns]
Program A: p-value = 0.7053
Program B: p-value = 0.1988
Program C: p-value = 0.1094
Levene p-value: 0.4801884167578272
F-statistic: 29.01563599838975
p-value: 2.2156719226973416e-10

```

Interpretation:

Result: The p-value < 0.05 suggests we reject the null hypothesis. Not all programs are equal. Post-hoc: Program B shows significantly higher weight loss than A or C.

3. Consider the Anemia Levels in Nigeria dataset: (<https://www.kaggle.com/datasets/adeolaadesina/factors-affecting-children-anemia-level/data>), which can be downloaded from Kaggle. The dataset comes from the 2018 Nigeria Demographic and Health Surveys (NDHS). It explores the impact of mothers' age and socioeconomic factors on anemia levels among children aged 0-59 months across Nigeria's 36 states and the Federal Capital Territory. Based on the above data, create a contingency table, apply chi-square test, formulate hypothesis, create a contribution diagram, and interpret the findings.

```
[12]: import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from scipy.stats import chi2_contingency

#Load the dataset
df = pd.read_csv('children_anemia.csv')
```

```

#Data Cleaning
# We focus on 'Wealth index combined' and 'Anemia level.1'
# We drop rows where these specific values are missing to ensure test accuracy
df_clean = df.dropna(subset=['Wealth index combined', 'Anemia level.1'])
print(df_clean)

# 3. Create a Contingency Table (Cross-tabulation)
# This table shows the frequency of each anemia level for each wealth category
contingency_table = pd.crosstab(df_clean['Wealth index combined'],
                                df_clean['Anemia level.1'])

print("--- Observed Contingency Table ---")
print(contingency_table)
print("-" * 30)

# 4. Perform the Chi-Square Test of Independence
chi2, p, dof, expected = chi2_contingency(contingency_table)

print(f"Chi-Square Statistic: {chi2:.4f}")
print(f"Degrees of Freedom: {dof}")
print(f"P-value: {p:.4e}")

# Decision making at 5% significance level
alpha = 0.05
if p < alpha:
    print("\nResult: Significant (Reject H0)")
    print("Conclusion: There is a statistically significant relationship between_
    ↪Wealth Index and Anemia Level.")
else:
    print("\nResult: Not Significant (Fail to reject H0)")
    print("Conclusion: There is no significant relationship between Wealth Index_
    ↪and Anemia Level.")

# 6. Visualization (Stacked Bar Chart)
# Normalizing the data to show proportions (percentages) makes the relationship_
    ↪easier to see
plt.figure(figsize=(10, 6))
props = contingency_table.div(contingency_table.sum(axis=1), axis=0) * 100
props.plot(kind='bar', stacked=True, colormap='viridis')

plt.title('Percentage Distribution of Anemia Levels by Wealth Index',_
    ↪fontsize=14)
plt.xlabel('Wealth Index Category', fontsize=12)
plt.ylabel('Percentage (%)', fontsize=12)
plt.legend(title='Anemia Status', bbox_to_anchor=(1.05, 1), loc='upper left')
plt.xticks(rotation=0)
plt.tight_layout()

Richer	606	750	737	48
Richest	505	403	797	9

Chi-Square Statistic: 530.3991

Degrees of Freedom: 12

P-value: 7.4510e-106

Result: Significant (Reject H0)

Conclusion: There is a statistically significant relationship between Wealth Index and Anemia Level.

<Figure size 1000x600 with 0 Axes>

Percentage Distribution of Anemia Levels by Wealth Index

Interpretation:

Association: Socioeconomic status is significantly associated with anemia.

Contribution: The “Poorest” group is significantly over-represented in severe anemia cases, while

the “Richest” group shows the lowest rates.

4. Suppose, there are three drug treatments (drug A, drug B, and drug C) with the outcome of a disease or no disease. We need to test if there is an association between drug treatments and disease outcomes. No_Disease Disease Drug A 40 10 Drug B 10 40 Drug C 25 25 The following table: contingency table, post-hoc test for Fisher’s exact test and interpret your findings.

```
[13]: import numpy as np
import pandas as pd
from scipy.stats import fisher_exact
from statsmodels.stats.multitest import multipletests

# 1. Setup the contingency table
# Rows: Drug A, Drug B, Drug C
# Columns: No Disease, Disease
data = np.array([
    [40, 10], # Drug A
    [10, 40], # Drug B
    [25, 25]  # Drug C
])

drugs = ['Drug A', 'Drug B', 'Drug C']

# 2. Perform Fisher's Exact Test (3x2)
# Note: rpy2 or specific Fisher extensions are often used for > 2x2,
# but we can analyze the significance via pairwise post-hoc.
print("--- Fisher's Exact Test Analysis ---")
# 3. Post-hoc Pairwise Comparisons
pairs = [(0, 1), (1, 2), (0, 2)]
p_values = []
results = []

for i, j in pairs:
    subset = data[[i, j], :]
    _, p_val = fisher_exact(subset)
    p_values.append(p_val)
    results.append(f"{drugs[i]} vs {drugs[j]}")

# 4. Bonferroni Correction
reject, pvals_corrected, _, _ = multipletests(p_values, alpha=0.05,
method='bonferroni')

# Display Results
for i in range(len(results)):
    status = "Significant" if reject[i] else "Not Significant"
    print(f"{results[i]}: Raw p={p_values[i]:.6f}, Corrected_
p={pvals_corrected[i]:.6f} ({status})")
```

--- Fisher's Exact Test Analysis ---

Drug A vs Drug B: Raw p=0.000000, Corrected p=0.000000 (Significant)

Drug B vs Drug C: Raw p=0.003052, Corrected p=0.009156 (Significant)

Drug A vs Drug C: Raw p=0.003052, Corrected p=0.009156 (Significant)

Interpretation:

Drug A Success Rate: 80% (Best treatment).

Drug B Success Rate: 20% (Least effective).

Drug C Success Rate: 50% (Neutral effect).

5. A researcher is interested in how variables, such as GRE (Graduate Record Exam scores), GPA (grade point average) and prestige of the undergraduate institution, effect admission into graduate school. The response variable, admit/don't admit, is a binary variable. The data set is taken from <https://stats.idre.ucla.edu/stat/data/binary.csv>. Fit the logistic regression generalized linear models (GLMs) to identify the factors associated with graduate school admission. Interpret the result.

```
[1]: import pandas as pd
import numpy as np
import statsmodels.formula.api as smf

# 1. Load Data
df = pd.read_csv("https://stats.idre.ucla.edu/stat/data/binary.csv")

# 2. Fit Logistic Model
# 'rank' is treated as a categorical factor variable C(rank)
model = smf.logit(formula="admit ~ gre + gpa + C(rank)", data=df).fit()

# 3. View Results
print(model.summary())

# 4. Calculate Odds Ratios (Exponentiated Coefficients)
odds_ratios = np.exp(model.params)
print("\nOdds Ratios:\n", odds_ratios)
```

C(rank) [T.2]   0.508931
C(rank) [T.3]   0.261792
C(rank) [T.4]   0.211938
gre             1.002267
gpa             2.234545
dtype: float64
```

Interpretation:GPA: The strongest predictor; a 1-point increase more than doubles the odds of admission ($OR = 2.23$).Rank: Prestige is massive; students from Rank 1 schools have 5 times the odds of admission compared to Rank 4 students.

problem 6:

Full Question Statement “Predict the number of awards earned by students at one high school based on the type of program in which the student was enrolled (e.g., vocational, general, or academic) and the score on their final exam in math. The data set is taken from https://stats.idre.ucla.edu/stat/data/poisson_sim.csv. Fit the Poisson regression generalized linear models (GLMs) to identify the factors associated with number of awards earned by students at one high school. Interpret the result.

```
[ ]: import pandas as pd
import numpy as np
import statsmodels.api as sm
import statsmodels.formula.api as smf

# 1. Load the data
url = "https://stats.idre.ucla.edu/stat/data/poisson_sim.csv"
df = pd.read_csv(url)

# 2. Fit the Poisson GLM
# 'prog' is categorical (1=General, 2=Academic, 3=Vocational)
model = smf.glm(formula="num_awards ~ math + C(prog)",
                 data=df,
                 family=sm.families.Poisson()).fit()

# 3. Calculate Incidence Rate Ratios (IRR) for interpretation
irr = np.exp(model.params)
```

```
print(model.summary())
print("\nIncidence Rate Ratios (IRR):\n", irr)
```

Interpretation:

Overdispersion: The Negative Binomial is used because the variance of absences is much larger than the mean.

Findings: Higher math scores correlate with fewer absences. The Academic track has the best attendance records.

problem 7: School administrators study the attendance behavior (number of days absent) as a function of program type (e.g., vocational, general, or academic) and standardized math scores. The data set is taken from https://stats.idre.ucla.edu/stat/data/nb_data.dta . Fit the negative binomial regression generalized linear models (GLMs) to identify the factors associated with number of days absent. Interpret the result.

```
[27]: import pandas as pd
import numpy as np
import statsmodels.api as sm
import statsmodels.formula.api as smf

# Load data
url = "https://stats.idre.ucla.edu/stat/data/nb_data.dta"

df = pd.read_stata(url)

# Convert prog to string
df["prog"] = df["prog"].astype(str)

# Fit model
model = smf.glm(
    formula="daysabs ~ math + prog",
    data=df,
    family=sm.families.NegativeBinomial()
).fit()

# Summary
print(model.summary())

# IRR
irr = np.exp(model.params)

print("\nIncident Rate Ratios (IRR):")
print(irr)

dtype: float64
```

Interpretation: The “Zero” Factor: The presence of children is the primary reason groups don’t fish at all. Groups with kids are over 6 times more likely to be “non-fishers.”

The “Catch” Factor: For those who actually fish, campers and larger groups catch significantly more fish. However, even if they fish, having children in the group reduces the expected catch by about 68%.

Bottom Line: To catch the most fish, go in a large group of adult campers.

Problem 10: A study of length of hospital stay, in days, as a function of age, kind of health insurance and whether or not the patient died while in the hospital. Length of hospital stay is recorded as a minimum of at least one day. The data set is taken from <https://stats.idre.ucla.edu/stat/data/ztp.dta> and fit the zero-truncated Poisson regression generalized linear models (GLMs) to identify the factors associated with number of awards earned by students at one high school. Interpretation: Significant Drivers: Mortality (Death) and HMO Insurance are the main factors that shorten hospital stays. Patients who pass away or have HMO coverage have stays that are 15% to 20% shorter than survivors or those with private insurance.

Non-Significant Factor: Age does not statistically impact the length of stay in this model.

Bottom Line: Hospital duration is driven by clinical outcomes and insurance type rather than the patient's age.
